

AutoPilotYield

A 10L%o ep0Á0§0ü0ó0nR)VP0Š0'•êRŒ0g]áVP0û•Ku(0Y0<N R' b@_—0Ü0ë0È

The Problem & Our Solution

Manually tracking and rebalancing yield across chains is slow and requires deep DeFi expertise.

- DeFi yields shift constantly across Solana, Ethereum, and other chains
- Most users lack the time or expertise to monitor and rebalance positions
- AutoPilotYield lets an AI agent handle discovery and rebalancing automatically
- Users deposit once into a Solana vault and get hands-off multi-chain yield

How It Works

A simple deposit flow backed by AI scoring, cross-chain bridging, and transparent on-chain execution.

- User deposits assets into the Solana vault and picks a risk profile
- AI agent scores yield opportunities on Solana and Ethereum using oracle/API data
- Agent triggers rebalancing transactions via Wormhole to move funds cross-chain
- Vault contract executes deposits, withdrawals, and allocation changes on-chain
- Dashboard shows current allocation, APY, and full rebalancing history

Built with

Solana, Ethereum, Wormhole, Anchor, Rust, Wormhole SDK, Python/LLM agent

Why Now & What's Next

Mature cross-chain infra and AI agent frameworks make autonomous, on-chain yield execution possible today.

- Bridges like Wormhole now make cross-chain execution reliable and fast
- AI agent frameworks can combine reasoning with real transaction execution
- Next: add more chains and yield protocols for broader coverage
- Next: add backtesting and strategy audits to build trust
- Next: launch tokenized vault shares for liquidity and composability
